Piglets less than 2 days old were challenged i.v. with a suspension of P. aeruginosa containing 10⁷ colony-forming units (cfu/ml). Lung tissue samples were obtained at intervals up to 120 h post challenge. The morphological features of the lung were investigated by light and electron microscopy. Some cells showing features of activation were observed in the alveolar space. The number of these cells increased up to 6 h post challenge. At later time-points the number of cells with these characteristics declined to very low levels. The differences were significant (P less than 0.01) between 6 and 48 h. The lungs of challenged animals showed a number of early signs of inflammation such as increased vascular permeability. However, the lungs contained no neutrophils or macrophages that were associated with the alveolar wall and alveolar epithelium, and there were no obvious signs of lung injury. The alveolar lining fluid showed markedly increased permeability. The phagocytic activity of the alveolar macrophages appeared to be depressed as indicated by reduced numbers of phagocytosed particles. 1 3 * f - 0 6 2 .
